INTRODUCTION

Cape Kennedy empirical wind component statistics are presently being used for aerospace engineering applications that require component wind probabilities for various azimuths and selected altitudes [1]. This document replaces the empirical statistics given in Reference 1 with theoretical statistics using the normal (Gaussian) distribution as an acceptable statistical model for component winds for altitudes 0 to 70 km at Cape Kennedy, Florida. The tables are presented in a format that is analogous to that given in Reference 1. Tabulations for all months, January through December, are included. The normal distribution was not applied to the annual reference period since this is a heterogeneous sample and should not be represented by a univariate statistical model. If statistics are required for the annual reference period, it is recommended that the empirical statistics [1] be used.

Tables 1.1 through 1.12 present bivariate normal statistics for all months for the 90 degree flight azimuth. Tables 2.1 through 13.12 present head- and tailwind components and right and left crosswind components for all altitudes 0 through 70 kilometers for flight azimuths ranging from 30 degrees to 105 degrees in 15-degree increments. Head- and tailwinds are coincident with flight azimuth; right and left crosswinds are orthogonal to flight azimuth. Considering head- and tailwinds for a given flight azimuth, a negative wind indicates a headwind and a positive wind indicates a tailwind. Also, for right and left crosswinds, a negative wind indicates a left crosswind while a positive wind indicates a right crosswind. All wind components are in meters per second. Symmetry allows one to obtain all 15-degree incremental flight azimuths not given in the tables from the following tabulation.

THE NORMAL DISTRIBUTION

The normal distribution has many advantages for use as a statistical model to represent random variables. It is the best known and most useful distribution in mathematical statistics. Its probability density function is

$$f(x) = \frac{1}{\sigma \sqrt{2\pi}} \exp \left[-\frac{(x - \mu)^2}{2\sigma^2} \right] , \quad (1)$$

$$-\infty < x < \infty , \quad -\infty < \mu < \infty , \quad \sigma > 0 ,$$

where μ and σ are location and scale parameters, respectively, of the distribution. μ is the mean and σ is the standard deviation. Normal distributions with different values of μ and a common σ , and with different values of σ for a common μ are shown in Figures 1 and 2, respectively. All normal distributions are symmetric and have the same bell-type shape.

The cumulative normal distribution function is

$$F(x) = \frac{1}{\sigma \sqrt{2\pi}} \int_{-\infty}^x \exp \left[-\frac{(z - \mu)^2}{2\sigma^2} \right] dz . \quad (2)$$

The distribution function [equation (2)] gives the probability of a randomly selected value from a normal distribution with parameters μ and σ being less than or equal to x . This cumulative probability is the "cumulative percentage probability" or "percentiles" given in the tables. The random variable x (wind components in meters per second) is given in the body of the tables. To relate percentiles to the normal distribution function, one may use:

<u>Normal Distribution</u>	<u>Percentile</u>
Mean - 3 standard deviations	0.135
Mean - 2 standard deviations	2.280
Mean - 1 standard deviation	15.900
Mean	50.000
Mean + 1 standard deviation	84.100
Mean + 2 standard deviations	97.720
Mean + 3 standard deviations	99.865

ANALYSIS

Two data samples were used in this analysis. The sample for altitudes 0 to 27 km consists of 12 years of serially complete radiosonde observations taken twice daily. The period of record is January 1, 1956, to December 31, 1967. The data sample for altitudes 28 to 70 km consists of all rocketsonde observations currently available. The period of record is January 1, 1960, to December 31, 1967.

Figure 3 shows the range of azimuths for which the tables in this document may be used. All data used in this study were recorded as vector winds (wind speed and corresponding direction). The vector winds were subsequently resolved into components along the azimuths $\alpha = 90$ degrees and $\alpha = 360$ degrees (true north).

The bivariate normal statistics for all months for the 90 degree flight azimuth ($\alpha = 90$ degrees) are given in Tables 1.1 through 1.12. For this flight azimuth, standard meteorological notation defines u as the zonal wind component and v as the meridional wind component. In this study, u is the headwind component while v is the crosswind component. The sample estimates of the theoretical mean μ are \bar{u} and \bar{v} . The sample estimates of the theoretical standard deviation σ are $S(u)$ and $S(v)$. $R(uv)$ is the sample estimate of the theoretical correlation coefficient between u and v . $S(uv)$ is the covariance of u and v . N is the sample size.

Available rocketsonde data above 60 km were considered to be too sparse to give valid representative statistics for this study. For this reason linear interpolations for the required statistics (Tables 1.1 through 1.12) were made from 60 km to estimates of the parameters at 70 km. The estimates of the means \bar{u} and \bar{v} at 70 km were made using the profile of strongest monthly 50th percentiles. This profile established a strongest monthly 50th percentile at 60 km and another at 70 km. Now, the means for each month were assumed to decrease with altitude at the same rate as these two means decreased with altitude. The monthly standard deviations $S(u)$ and $S(v)$ at 70 km were estimated by choosing the magnitudes of the standard deviations below 60 km that corresponded to the estimated values of the means at 70 km. For example, if the estimated mean at 70 km was 27 m/sec, then the standard deviation below 60 km that corresponds to a mean of 27 m/sec was used for the standard deviation at 70 km. The correlation coefficient $R(uv)$ above 60 km was assumed to be zero due to lack of data and the general trend of the correlation coefficient with increasing altitude appeared to be approaching zero.

(NOTE: IF THE DESIRED FLIGHT AZIMUTH FALLS ON A LINE OF SEPARATION, CHOOSE THE α TOWARDS THE E-W AXIS. DIRECTION AZIMUTHS ARE WITH REFERENCE TO TRUE NORTH.)

Figure 3. Range of azimuths for which the published values should be used without interpolation.

The five statistics \bar{u} , \bar{v} , $S(u)$, $S(v)$ and $R(uv)$ completely define a bivariate normal elliptical distribution. Using these five parameters at azimuth $\alpha = 90$ degrees, the statistics for any rotation of axes of the bivariate normal surface may be obtained [2]. This method was used to compute the means and standard deviations required for the normal distribution at the other required azimuths $\alpha = 30, 45, 60, 75$ and 105 degrees.

The Kolmogorov-Smirnov (KS) test was used to determine goodness of fit in this study for a number of reasons. This test is superior to the familiar Chi-Square (χ^2) test in several ways. When samples are of moderate size and adjacent categories must be combined before χ^2 may properly be computed, the χ^2 test is definitely less powerful than the KS test. For the χ^2 test, when adjacent categories must be combined, one is sometimes faced with the impossible problem of zero or negative degrees of freedom for the test, which means simply that no valid test exists. For very small samples, the χ^2 test is not appropriate at all, but the Kolmogorov-Smirnov test is. Siegel [3] states that "the Kolmogorov-Smirnov test may in all cases be more powerful than its alternative, the χ^2 test."

CONCLUSIONS

Care must be exercised in making decisions about which is a "best" model for a random variable. The question is not "Do the data come from some specified distribution?" because one can never be sure they do, but rather "Is some specified distribution a reasonable model for the description of the data?" If the physical constraints for the random variable are satisfied by a hypothetical distribution and after repeated sampling of this random variable it is found that the hypothetical distribution cannot be rejected by an appropriate statistical test, then one may reach the conclusion that this hypothetical distribution is an adequate model for the random variable under investigation.

Wind velocity components are variables that are unbounded at both ends. This constraint is satisfied by the normal distribution whose domain is from minus infinity to plus infinity. As mentioned previously, the use of the Gaussian model has many advantages. For example, if the wind components u and v are normally distributed, the scalar wind,

$$w = (u^2 + v^2)^{1/2} ,$$

has a noncentral chi distribution. From a theoretical point of view, this property of the normal distribution illustrates one of its many advantages as a statistical model to represent random variables.

The empirical wind component distributions for Cape Kennedy for all months for altitudes 0 to 70 km were tested using the Kolmogorov-Smirnov goodness-of-fit statistic to determine whether the normal distribution could be rejected as a reasonable model for the data. Results of tests on distributions above 60 km cannot be considered significant due to lack of data. It was found that approximately 85 percent of the distributions tested could not be rejected at the 5 percent rejection level (95 percent confidence level). Hence, one may reach the conclusion that the normal distribution provides an adequate model for wind components at Cape Kennedy, Florida.
